

## Equilibrium

---

---

---

---

---

---

---

---

## Le Châtelier's Principle

- ~whenever stress is applied to a system at equilibrium, a new equilibrium will be obtained to relieve this stress.
- stress is a change in temperature, pressure, or concentration of some component.
- This will change the rate of reaction of either the forward or backward reaction
- So you will see an increase in the concentration of the substances on one side of the equation, and a decrease on the other.
- This will "shift" the equation to the right or left.

---

---

---

---

---

---

---

---

## Examples

- Endothermic reactions absorb heat, i.e. they need heat to react.
- If the solution is heated prior to the reaction (stress)...
- It will react more quickly
- So the equation will be forced to the right (product side)
- If the reaction is cooled, it will be forced to the left (reactant side)

---

---

---

---

---

---

---

---

## Equilibrium

- Systems at equilibrium are still dynamic (changing). However, no NET CHANGE will be observed.
- A system is at equilibrium when the *rate of the forward reaction is equal to the rate of the reverse reaction.*

---

---

---

---

---

---

---

---

## Changing concentration

- $2 \text{H}_2\text{O} \rightleftharpoons \text{H}_3\text{O}^+ + \text{OH}^-$
- If I add more water
- It will force the reaction to the right
- Which means more hydronium and hydroxide will be produced
- This is dilution (making the ratio of hydronium/hydroxide closer)

---

---

---

---

---

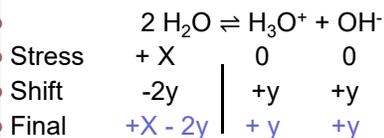

---

---

---

## Equilibrium

Add water

\*where X is the amount of  $\text{H}_2\text{O}$  added

Since the stress was added to the left, we must take from the left and give to the right to relieve the stress

\*y is the amount of water that "shifts" over to make more hydronium and hydroxide. For every 2  $\text{H}_2\text{O}$  molecules, one  $\text{H}_3\text{O}^+$  and  $\text{OH}^-$  is produced

---

---

---

---

---

---

---

---

### What this means...

- Add water
- $2 \text{H}_2\text{O} \rightleftharpoons \text{H}_3\text{O}^+ + \text{OH}^-$
- Final  $+X - 2y \quad +y \quad +y$
- The overall amount of water increased because X is always larger than y (with any coefficient).
- We increased  $\text{H}_3\text{O}^+$  because +y is an increase
- We increased  $\text{OH}^-$  because +y is an increase
- The amount  $\text{H}_3\text{O}^+$  increased is equal to the amount  $\text{OH}^-$  increased

---

---

---

---

---

---

---

---

### $2 \text{H}_2\text{O} \rightleftharpoons \text{H}_3\text{O}^+ + \text{OH}^-$

- If I remove hydroxide from the solution...
- $2 \text{H}_2\text{O} \rightleftharpoons \text{H}_3\text{O}^+ + \text{OH}^-$
- Stress  $0 \quad 0 \quad -X$
- Shift  $-2y \quad +y \quad +y$
- Final  $-2y \quad +y \quad -X + y$
- $\downarrow \quad \uparrow \quad \downarrow$
- \*Where X is larger than 2y
- So removing hydroxide increases  $[\text{H}_3\text{O}^+]$ , only slightly decreases  $[\text{OH}^-]$ , and decrease the water

---

---

---

---

---

---

---

---

### Try This

- If I add an acid to the equilibrium...
- $2 \text{H}_2\text{O} \rightleftharpoons \text{H}_3\text{O}^+ + \text{OH}^-$
- Stress
- Shift
- Final

---

---

---

---

---

---

---

---

### More Le Châtelier's

- If I add an acid to the equilibrium...
- $2 \text{H}_2\text{O} \rightleftharpoons \text{H}_3\text{O}^+ + \text{OH}^-$
- Stress      0      +X      0
- Shift      +2y      -y      -y
- Final      +2y      +X-y      -y
- ↑              ↑              ↓
- \*Where X is larger than 2y
- so adding acid will decrease the [OH<sup>-</sup>], only slightly increase the [H<sub>3</sub>O<sup>+</sup> ], and increase water.

---

---

---

---

---

---

---

---

### Different equation

- Adding ammonia, NH<sub>3</sub>, to the equilibrium
- $2 \text{NH}_3 \rightleftharpoons 3 \text{H}_2 + \text{N}_2$
- Stress
- Change
- Final

---

---

---

---

---

---

---

---

### Different equation

- Adding ammonia, NH<sub>3</sub>, to the equilibrium
- $2 \text{NH}_3 \rightleftharpoons 3 \text{H}_2 + \text{N}_2$
- Stress      +X
- Change      -2y      +3y      +y
- Final      +X-2y      +3y      +y
- ↑              ↑              ↑
- \*where X is larger than 2y
- Everything increases
- Note that the amount H<sub>2</sub> increases 3x as much as N<sub>2</sub>

---

---

---

---

---

---

---

---

### With heat

- If I cool the following equilibrium
- $\text{Heat} + \text{Co}^{2+} + 4 \text{Cl}^- \rightleftharpoons \text{CoCl}_4^{2-}$
- Stress
- Shift
- Final

---

---

---

---

---

---

---

---

### With heat

- If I cool the following equilibrium
- $\text{Heat} + \text{Co}^{2+} + 4 \text{Cl}^- \rightleftharpoons \text{CoCl}_4^{2-}$
- Stress    -X    0    0    0
- Shift        +y    +4y    -y
- Final        +y    +4y    -y
- ↑        ↑        ↓
- So cooling the solution will cause more  $\text{Co}^{2+}$  &  $\text{Cl}^-$  and less  $\text{CoCl}_4^{2-}$  to form

---

---

---

---

---

---

---

---

### Law of chemical equilibrium

- For an equilibrium
- $a \text{A} + b \text{B} \rightleftharpoons c \text{C} + d \text{D}$
- $K = \frac{[\text{C}]^c [\text{D}]^d}{[\text{A}]^a [\text{B}]^b}$
- K is the equilibrium constant for that reaction.
- The [ ] mean concentration in molarity. Make sure those are square brackets and not parenthesis!!

---

---

---

---

---

---

---

---

### So for the equilibrium

- $\text{CS}_2(\text{g}) + 3 \text{O}_2(\text{g}) \rightleftharpoons \text{CO}_2(\text{g}) + 2 \text{SO}_2(\text{g})$
- The K expression is concentrations of products over the reactants
- Raised to the power of their coefficient.
- $K = \frac{[\text{CO}_2][\text{SO}_2]^2}{[\text{CS}_2][\text{O}_2]^3}$

---

---

---

---

---

---

---

---

### Determine the equilibrium expression

- For the following:
- $\text{Br}_2(\text{g}) \rightleftharpoons 2\text{Br}(\text{g})$
- $\text{N}_2(\text{g}) + 3\text{H}_2(\text{g}) \rightleftharpoons 2\text{NH}_3(\text{g})$
- $\text{H}_2(\text{g}) + \text{Br}_2(\text{g}) \rightleftharpoons 2\text{HBr}(\text{g})$
- $\text{HCN}(\text{aq}) \rightleftharpoons \text{H}^+(\text{aq}) + \text{CN}^-(\text{aq})$

---

---

---

---

---

---

---

---

### Determine the equilibrium expression

- For the following:
- $K = \frac{[\text{Br}]^2}{[\text{Br}_2]}$
- $K = \frac{[\text{NH}_3]^2}{[\text{N}_2][\text{H}_2]^3}$
- $K = \frac{[\text{HBr}]^2}{[\text{H}_2][\text{Br}_2]}$
- $K = \frac{[\text{H}^+][\text{CN}^-]}{[\text{HCN}]}$

---

---

---

---

---

---

---

---

### Problem

- $2\text{NH}_3(g) \rightleftharpoons \text{N}_2(g) + 3\text{H}_2(g)$
- Calculate the equilibrium constant for the above reaction if it comes to equilibrium with the following concentrations:  $\text{N}_2 = .59$  M,  $\text{H}_2 = 3.1$  M, and  $\text{NH}_3 = 1.03$  M

---

---

---

---

---

---

---

---

### Answer

- $K = \frac{[\text{N}_2][\text{H}_2]^3}{[\text{NH}_3]^2}$
- $K = \frac{.59[3.1]^3}{[1.03]^2}$
- $K = 17$

---

---

---

---

---

---

---

---

### Equilibrium by phase

- Equilibrium depends on the concentration of the reactants.
- We can calculate the concentration of a gas or of anything dissolved (aqueous).
- Insoluble solids or liquids won't have a concentration.
- They in essence are removed from the equilibrium.

---

---

---

---

---

---

---

---

### So using that

- What would the equilibrium expression look like for the following reaction?
- $2 \text{H}_2\text{O}_{2(l)} \rightleftharpoons 2 \text{H}_2\text{O}_{(l)} + \text{O}_{2(g)}$
- We ignore the liquids (and solids).
- $K = [\text{O}_2]$

---

---

---

---

---

---

---

---

### Water

- $2 \text{H}_2\text{O}_{(l)} \rightleftharpoons \text{H}_3\text{O}^+_{(aq)} + \text{OH}^-_{(aq)}$
- $K_w = [\text{OH}^-] [\text{H}_3\text{O}^+] = 1 \times 10^{-14}$
- $K_w$  is the equilibrium constant for water, it equals  $1 \times 10^{-14} \text{ M}$
- This is the equation we were using earlier!

---

---

---

---

---

---

---

---
